ABSTRACT

This paper presents the results of horizontal distance measurements within Long Valley caldera between August 1978 and August 1983. This interval included significant uplift and extension centered on the caldera's resurgent dome and a large increase in seismicity within and adjacent to the caldera's southern moat. Intracaldera horizontal control data associated with this activity both in space and in time are documented in this report.

INTRODUCTION

In 1975, Long Valley caldera was being studied as a potential geothermal resource (Muffler and Williams, 1975). In order to monitor horizontal deformation associated with the expected geothermal development, the U.S. Geological Survey established a horizontal control (EDM) network within the caldera in 1975. The network was measured five times between August 1975 and September 1978, but no changes were observed that were greater than 3 ppm (the uncertainty in the measurements).

On May 25, 1980, the onset of an exceptionally intense earthquake swarm heralded a pronounced increase in seismicity within the southern moat and south of the caldera. Subsequently it was determined that between August 1979 and August 1980 there had been a 270 mm uplift of the resurgent dome (Denlinger and Riley, 1984; Savage and Clark, 1982). This prompted the expansion of the intracaldera EDM network in May and August 1982. Many new lines were established in the western and southern portions of the caldera in order to brace the existing network and cover critical areas. Subsequent remeasurements of the entire network were made in August 1983 and January 1983, with a partial remeasurement in December 1982 (Denlinger and others, in press). The completely reduced distances for each set of measurements are presented in this report.

METHOD OF DATA COLLECTION

The equipment used to make all of the measurements is listed in Table 1. An HP3808A distance meter that was calibrated for a specific line of sight temperature and pressure was used to measure distances. Therefore it was necessary that each distance measurement be corrected for the temperature and pressure along the line of sight at the time of the measurement.

All network control points were set into bedrock outcrop with concrete, or were clamped onto 5/8 inch copper weld grounding rod driven to refusal. The control points of the horizontal distance network are shown relative to the caldera in figure 1. Latitude and longtitude values for all stations are given in Table 2, station coordinates relative to station CASA are given in Table 3, and station elevations are given in Table 4.

The procedures of data collection varied only in the method used to estimate line of sight temperatures and pressures for reduction of the laser determined distances. These atmospheric values were measured either at the endpoints and averaged, or measured along the line of sight from an airplane as the readings were taken (Table 1.). Each reoccupation of the network is placed in one or two separate tables. All data for a particular reoccupation period that are reduced using line of sight temperature and pressure control are in separate tables (i.e. August 1982) that are identified with the words "line of sight" in the title. Errors exceeding 3 ppm may result from comparing measurements made using line of sight corrections with measurements using endpoint corrections because of atmospheric temperature structures. Instrument and reflector height corrections were made to all values and reduced slope distances are mark to mark.

The completely reduced data are listed as slope distances in Tables 5 through 11. Since the measurement precision depends upon the precision of the atmospheric correction, the standard deviations differ and consequently are listed at the head of each table for the set of values within that table.

ACKNOWLEDGMENT

The authors are indebted to the Los Angeles Department of Water and Power, whose helicopter support and field expertise made much of this work possible, and to Mark Clark (U.S. Forest Service, Mammoth Lakes, CA) for his untiring and knowledgable field assistance.

Table 1. Equipment used to measure the intracaldera distances.

Distance meter: Hewlett Packard 3808A Ga-As amplitude modulated infrared laser.
Reflectors used: Hewlett Packard, Servco, Nikon
(glass constant = 30mm)
Tripods: Kern tripod with plumb rod.

Endpoint Atmospheric measurement:

Temperature: glass mercury thermometer hung with a wire from the tripod head, shaded from the sun with metal foil.
Range: -20 to +40 degrees Centigrade
Precision: $\pm$ 0.1 degrees Centigrade

Pressure: Wallace and Tiernan altimeter
Range: 0 to 15000 feet
Precision: $\pm$ 10 feet

No humidity correction

Line of Sight Atmospheric measurement:
a small fixed wing aircraft was used,
range of flight speeds; 100 to 150 km/hr

Temperature: Wingstrut mounted thermistors, two in parallel with different response times, (3 second and 0.5 second). Both thermistors were accurate to $\pm$ 0.1 degrees Centigrade.

Pressure: Cabin pressure was monitored with a pressure transducer.
Range: 0 to 15 psi absolute
Precision: $\pm$ .001 psi

No humidity correction.

Table 10. Slope distances in meters determined in January, 1983 using endpoint atmospheric measurements. Standard deviation = 3 ppm, but probably higher for some lines due to strong temperature inversion that existed during some of the measurements.
